CLIMATE CONSCIOUS
Deep architectural overhangs and a perforated brick screen block the summer sun in this Gurgaon home (left and below right); Siri Haus, Delhi is a restoration of a half-century-old structure (below left)

our projects, well-specified glazing alone has reduced peak summer cooling loads by 25 to 30 per cent, energy that never needs generating because it was never wasted.

The third element is what most homeowners underestimate. An AI-driven energy management system does not simply monitor, it governs. It learns when the family wakes and sleeps, reads the week's forecast and acts before you do. On a day forecast to hit 45 degrees, it pre-cools the home during morning solar peaks so that by afternoon, when the grid is most strained, the house is already ahead, surplus flowing to battery walls or back to the grid. The home runs its own energy economy, increasingly better than its occupants would.

For Indian homeowners, the returns are real: elimination of utility bills, resilience against NCR power cuts, an asset that appreciates as energy costs rise. For architects, it demands a different discipline—orientation, simulation and integration, with the MEP consultant at the table before the sections are drawn.

The technology exists. The climate more than justifies it. What has been slower to arrive is the willingness to treat the home not as a container for modern life, but as a participant in it.

A home that produces more than it consumes is not a utopian idea. It is simply a better-designed one.
