REIMAGINING THE CLASSROOM

When used thoughtfully, AI does not make management education easier; it makes it richer, faster, and more realistic.

The century-old case study method can evolve into a dynamic business laboratory. Students can modify pricing decisions, respond to supply-chain disruptions or manage reputational crises while watching simulated markets react in real time.

AI also addresses one of the biggest classroom challenges: diverse student backgrounds. Engineers often struggle with organisational behaviour, while humanities graduates wrestle with financial accounting. AI can function as an always-available tutor, generating personalised practice and explanations, allowing faculty to devote classroom time to discussion, debate, and mentorship.

The gains extend beyond teaching. Students can analyse market reports, compare business models, and accelerate entrepreneurial experimentation at minimal cost. But the real educational value is not gathering information faster; it is learning how to question, verify, and interpret it.

WHERE AI CANNOT REPLACE THINKING

The greatest danger is not that AI will replace managers—it is that students may outsource thinking. An AI-generated strategy memo may appear polished while resting on hallucinated figures, weak assumptions or flawed economic reasoning. Business schools must therefore draw clear boundaries. Prompt engineering is a useful skill, but it cannot substitute for understanding corporate finance,
